DBD'14, Oct. 6, 2014 @ Hawaii, USA

# Directional Dark Matter Search

Annual Modulation

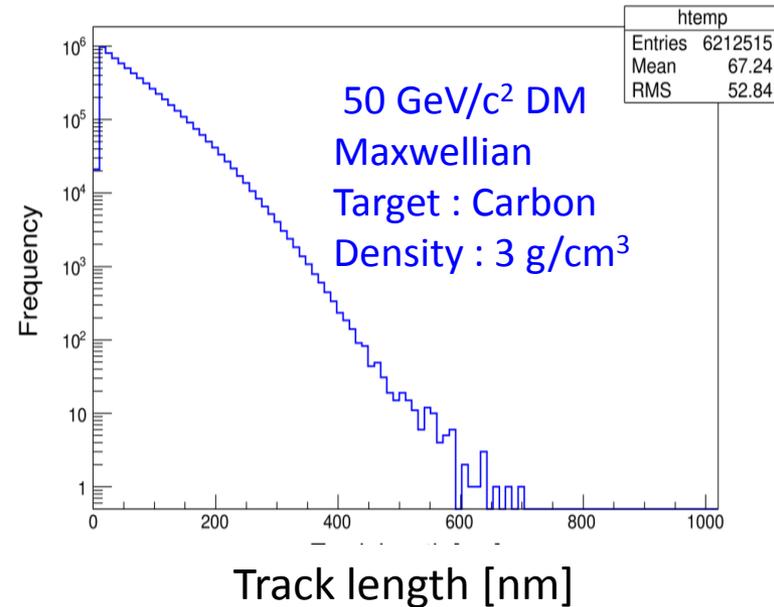

Asymmetry of angular distribution

- ✓ different information to identify the dark matter
- ✓ Identification with lower statistics (several 10 events) is possible from the asymmetry observation

# What is the direction sensitive detector with scalability?

## Challenge !!

- ✓ Spin-dependent search is done by gaseous Detector  $\Leftrightarrow$  spin-independent search ?
- ✓ Large mass detector with solid or liquid detector
  - $\Rightarrow$  very high spatial resolution ( $< 1 \mu\text{m}$ )
- ✓ Direction sensitive detector for nuclear recoil energy regions
  - $\Rightarrow$  enough angular resolution ( $< \sim 45 \text{ deg.}$ ) for very short length tracks

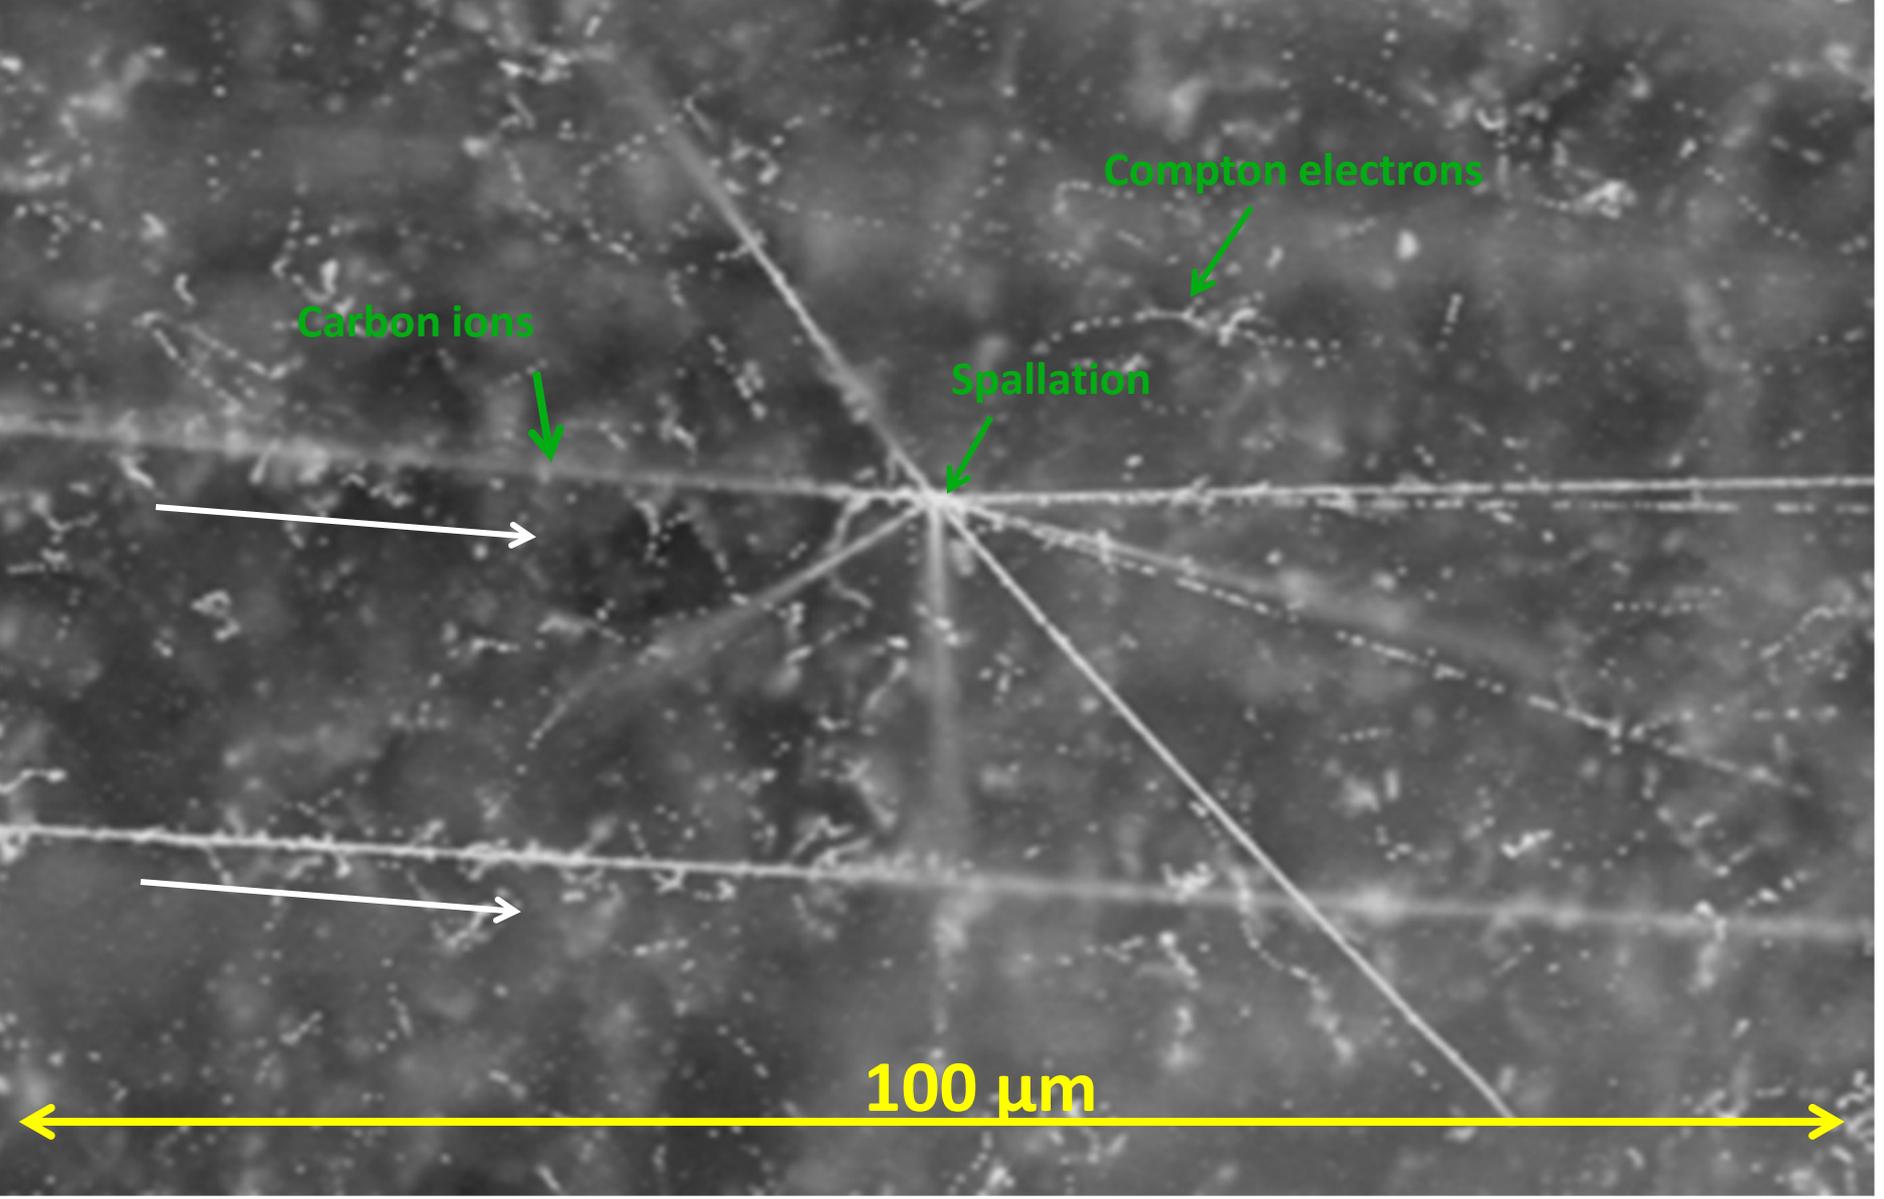

Can we make the direction sensitive detector with solid state ?

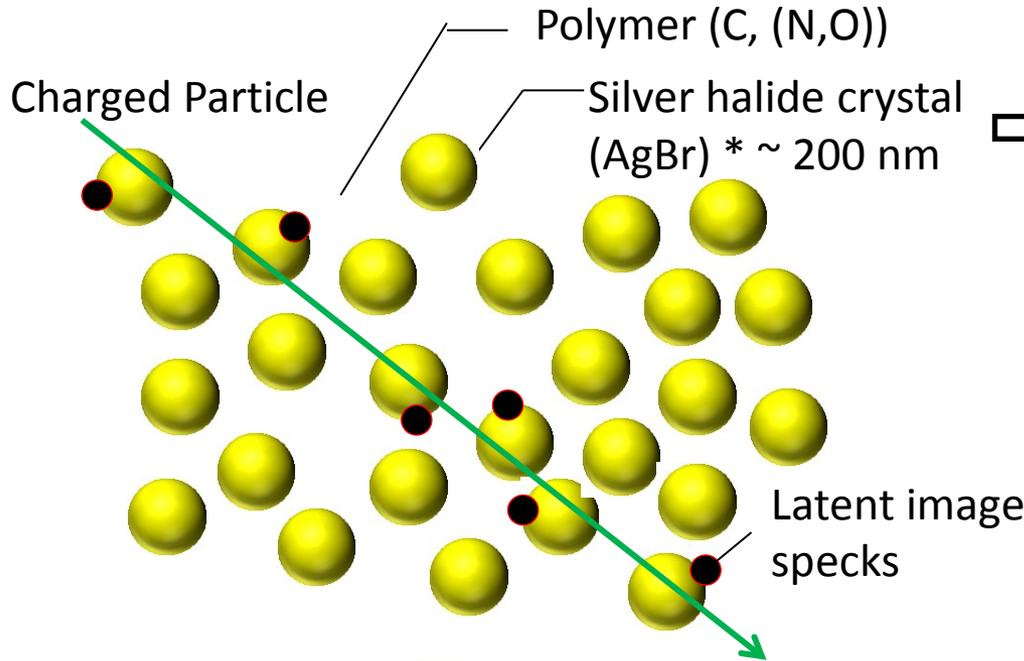

**Special detector based on the nuclear emulsion**

# Nuclear spallation reaction by Carbon ion ( $\sim \text{MeV/n}$ )

# Detection Principle of emulsions detector

⇒ Semiconductor (VG ~ 2.7 eV)

□ Spatial resolution  
⇒ Crystal size and density

□ Angular Resolution  
⇒ crystal size

For example, in the case of usual type,

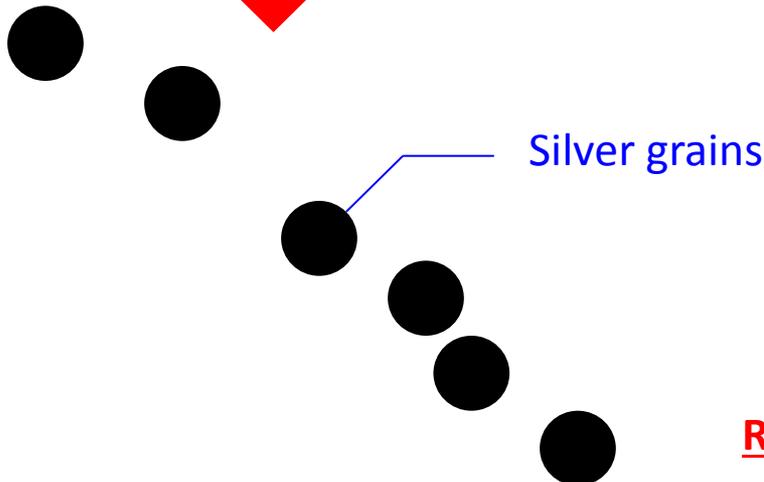

Crystal size : 200 nm ( $\sigma \sim 10$  nm)  
Density : 2.8 g/cm<sup>3</sup>  
(Vol. occupancy of crystal : 30 %)

2.4 crystals /  $\mu$ m

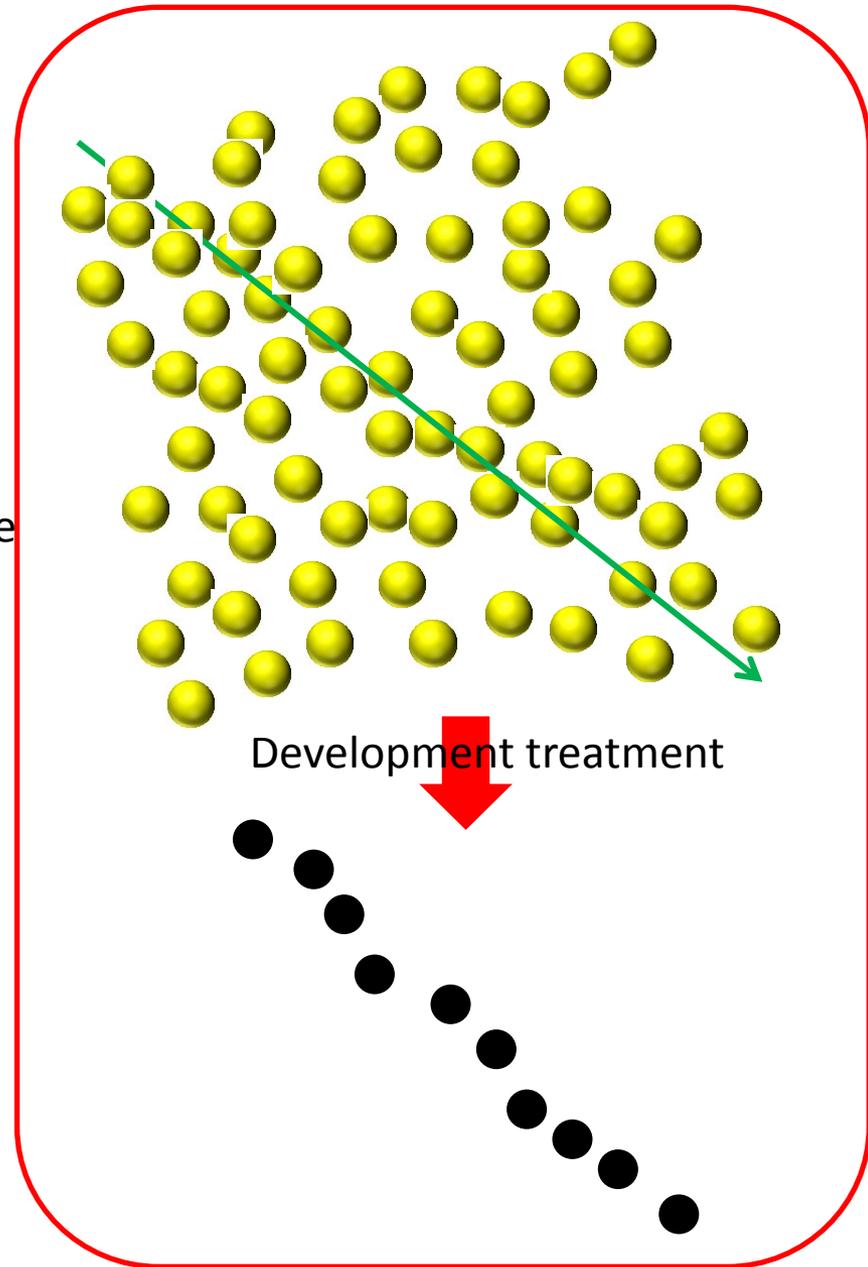

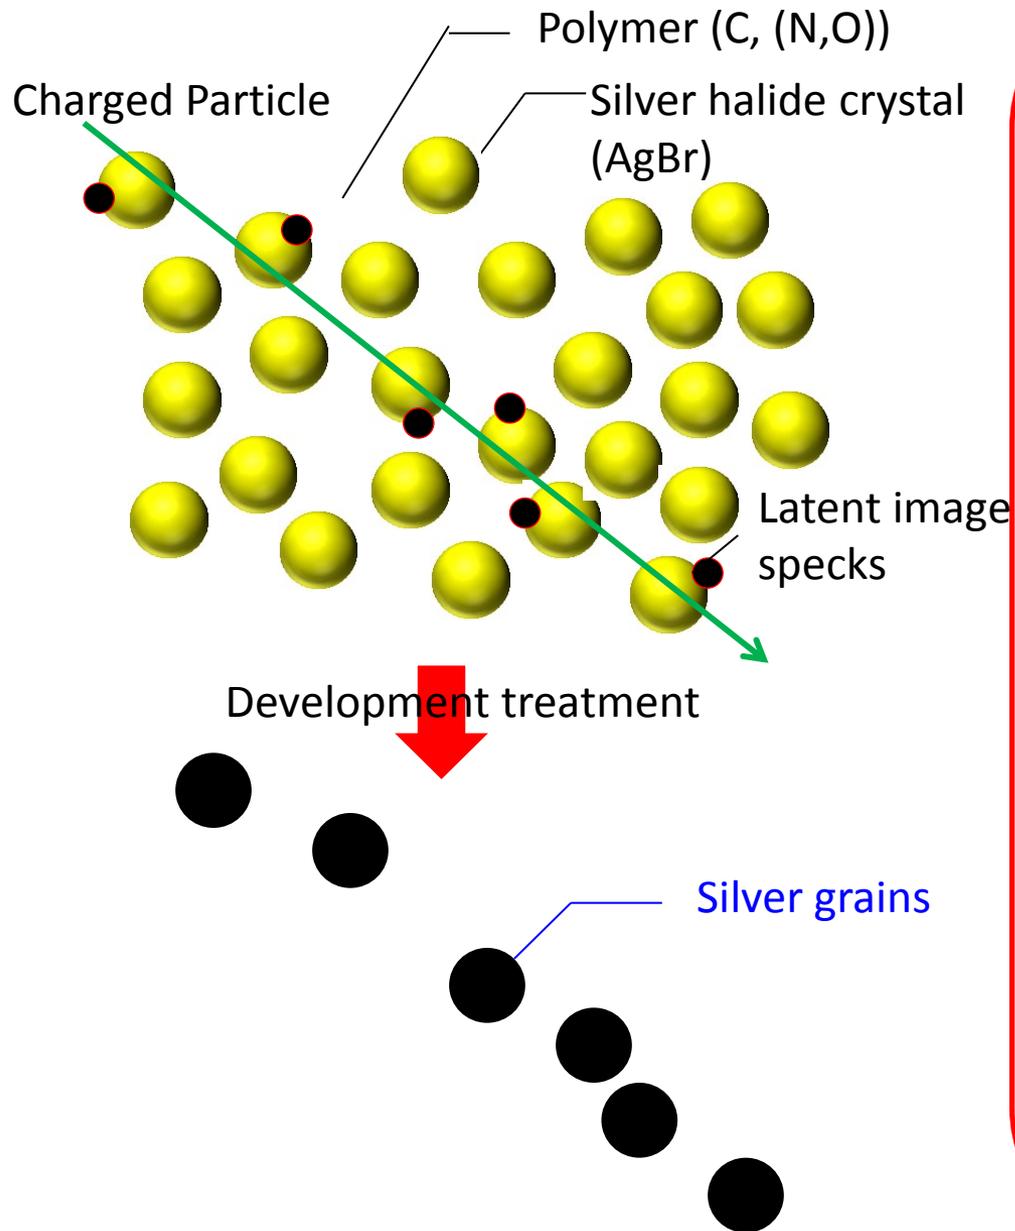

Detectable more than  $\mu$ m order!!

Development treatment

Resolution is poor yet for directional DM search.

# Higher resolution

# Device Self-Production

## 1<sup>st</sup> Machine installed from 2010

Production scale : 1 kg detector / week  
Very low-cost device : 1.5K \$ /kg

- crystal size control
- control of Q.E. for the crystal
- R&D for low-background

### Weight occupancy

AgBr·I : 74 %

Ag (42 %), Br (31 %), I (1 %)

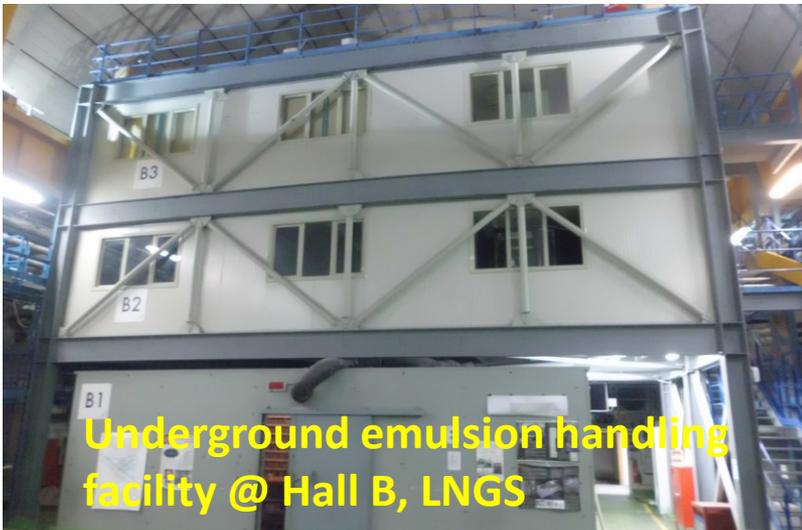

Binder (gelatin + PVA) : 25 %

C (10 %), N (4%), O (10 %), others (2%)

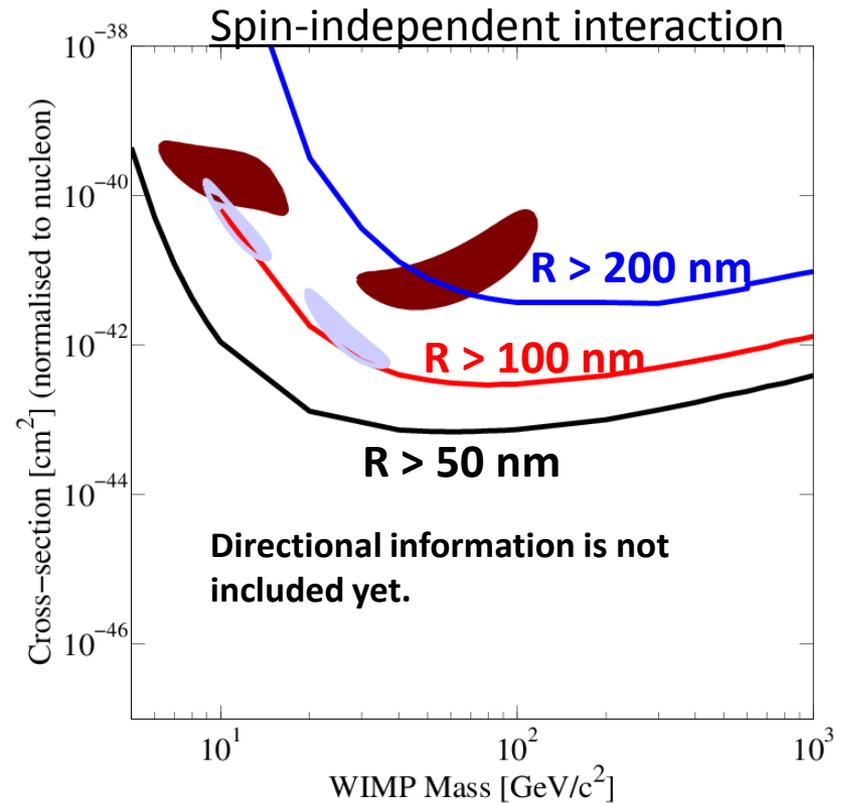

□ Good scalability  
⇒ no limitation for several kg scale  
⇒ > 10 kg may be needed the production machine

□ No time resolution ( disadvantage)  
⇒ CYGNUS tracking by the mount of the equatorial telescope

□ Underground production and chemical development

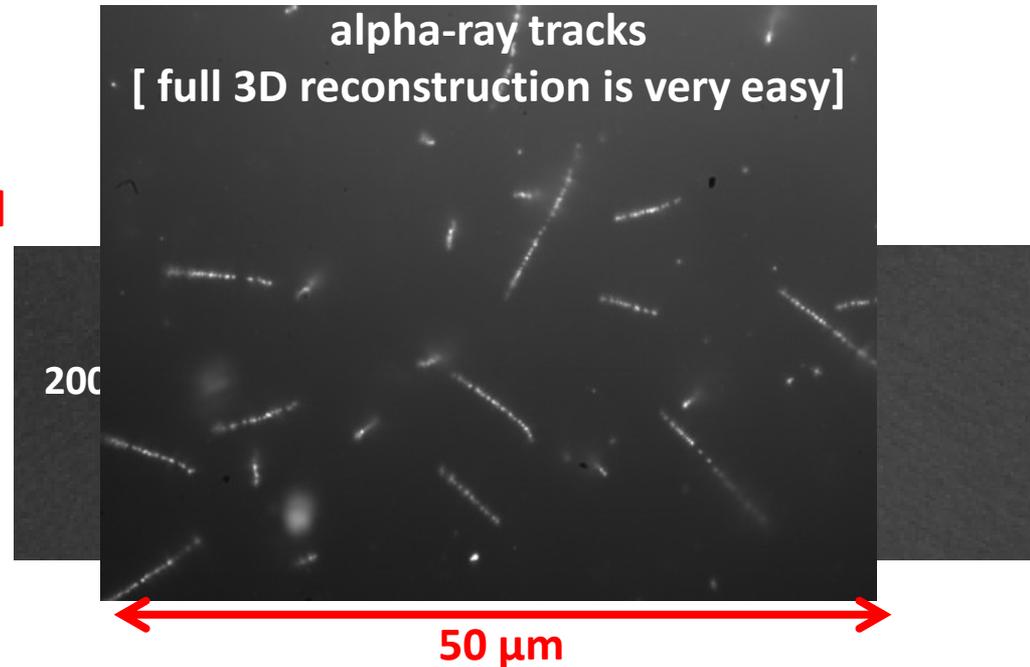

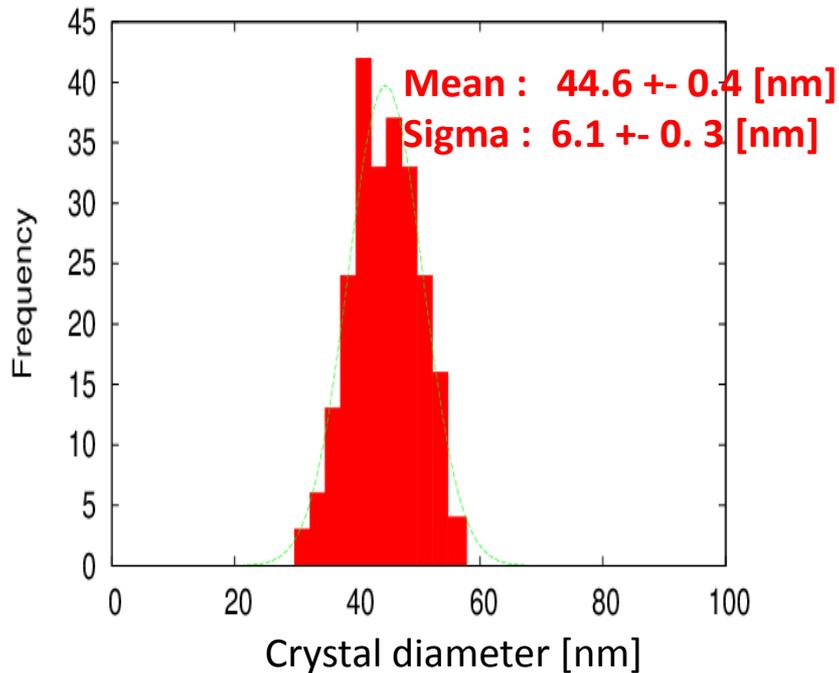

25 kg·y, 90 % C.L. , ideal predicted sensitivity

# Super-High Resolution Device

Nano Imaging Tracker : NIT

Current R&D emulsion

Detector density : 3.2 +/- 0.1 g/cm<sup>3</sup>

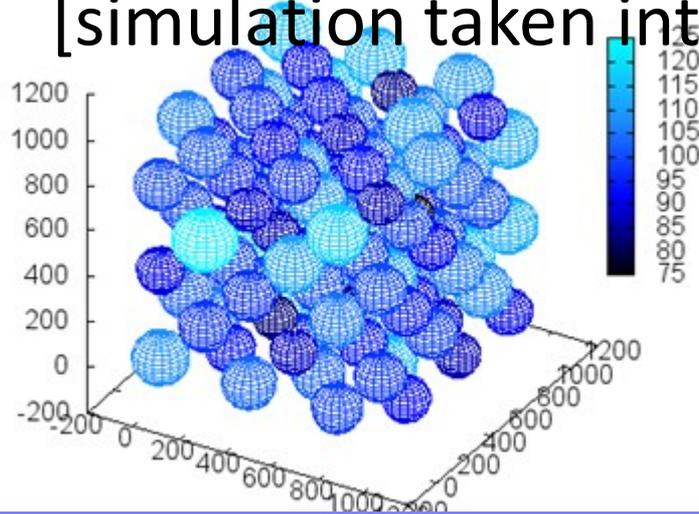

Mean # of crystal per length : 13 crystals/μm

## Research subject

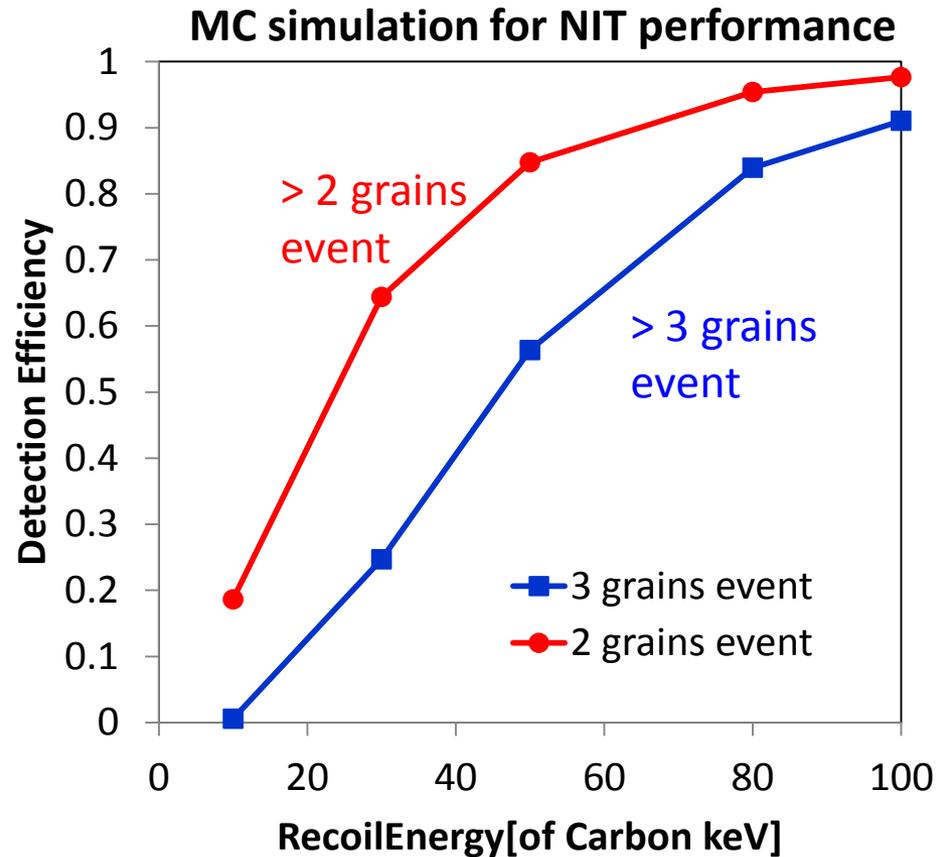

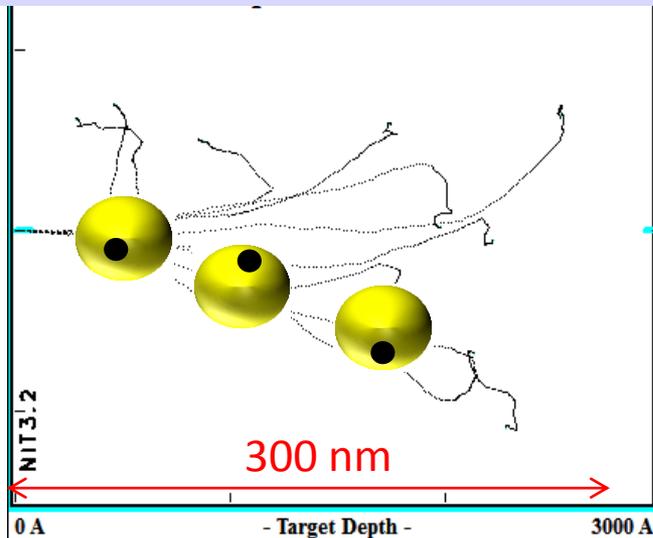

- Estimation of detector performance
- New readout technology for very short length tracks
- Lower background device and background rejection technologies

# Performance Potential of the Detector

[simulation taken into account the local structure]

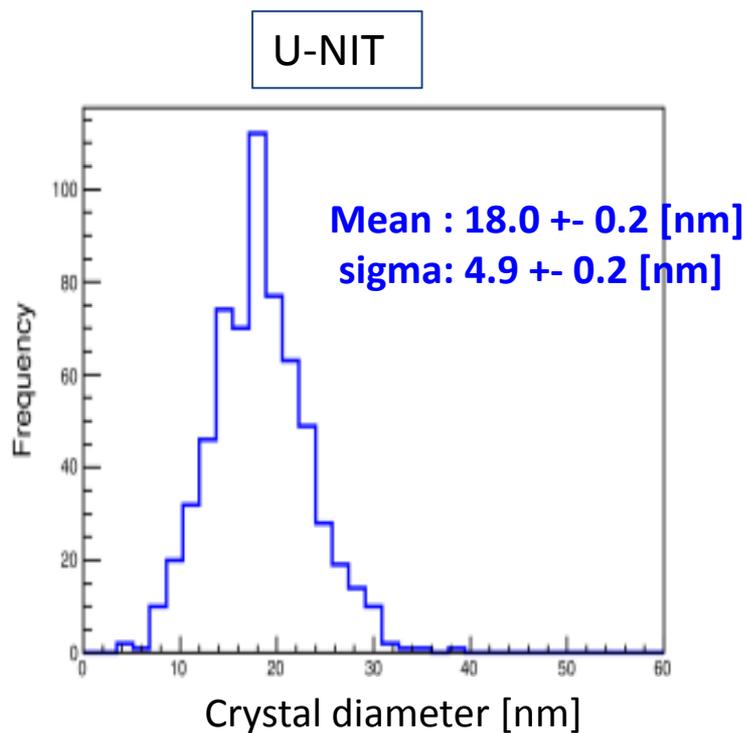

Mean crystal size : 43 nm  
( $\sigma$  of size dispersion 5.8 nm)  
Volume occupancy of crystal : 39.6 %

> 2 grain tracks : 25 keV @ 50% eff.  
> 3 grains tracks : 50 keV @ 50 % eff.  
⊗ 40 nm AgBr crystal

# Potential of further device

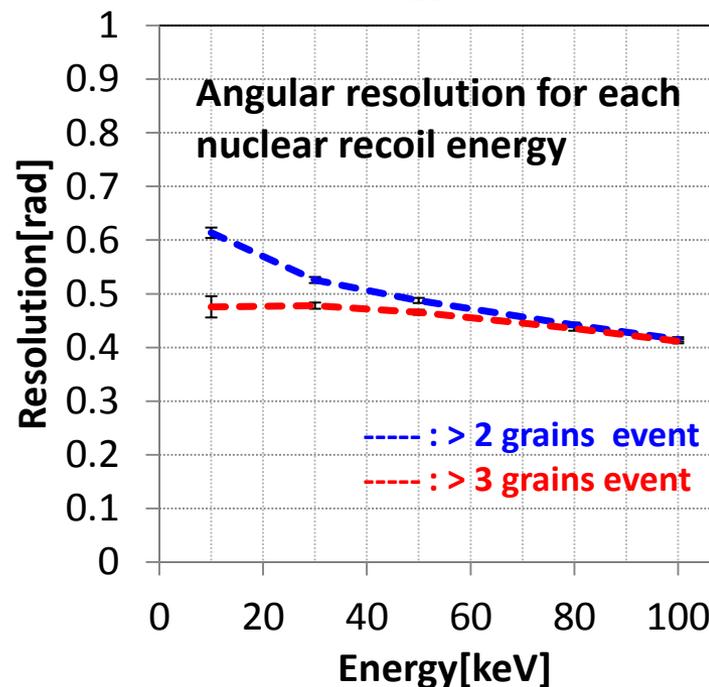

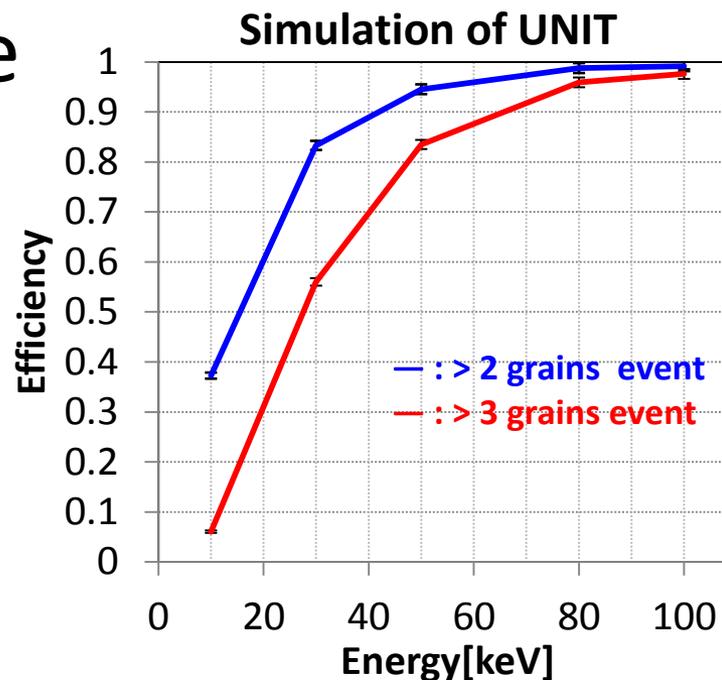

Further detector for physics run

Crystal control have already been confirmed!!

> 2 grains event : 15 keV Eth @ 50 % eff.  
then  $\Delta\theta \sim 33^\circ$

> 3 grains event : 30 keV Eth @ 50 % eff.  
then  $\Delta\theta \sim 27^\circ$

# Detector Analysis

## [Readout technology]

Combined system between high-speed selection and high-precision system

Large volume scanning

Optical microscope system

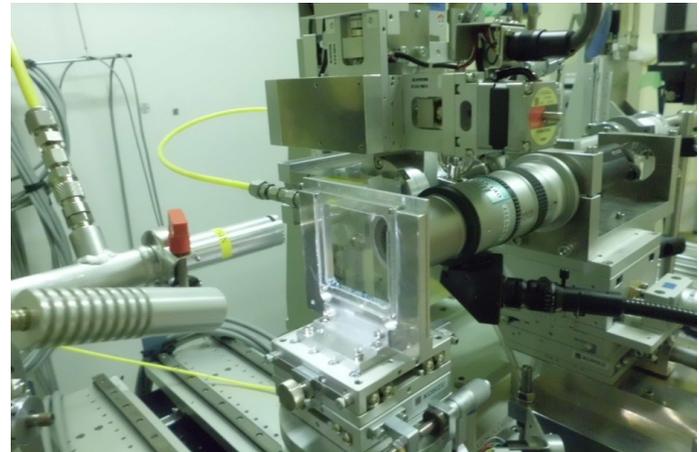

- ✓ High-speed scanning
- ✓ roughly candidate selection

Finally, ton scale readout !

But, poor resolution.

Spatial :  $\sim 195$  nm ( limited by Reyleigh criterion )

High-resolution analysis

X-ray microscope system

@ SPring-8 (Synchrotron radiation ring)

Spatial Resolution : 60 nm

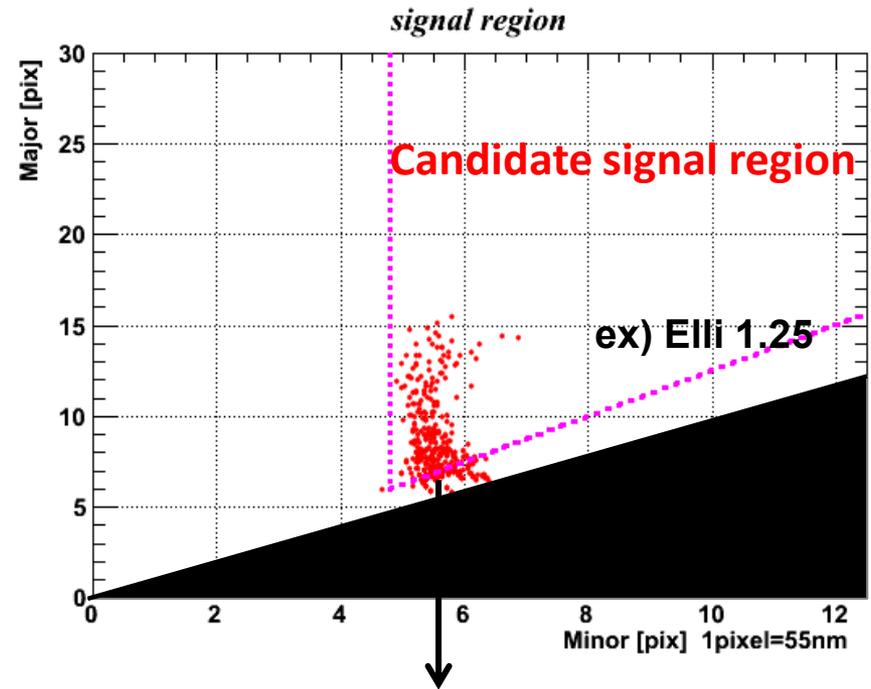

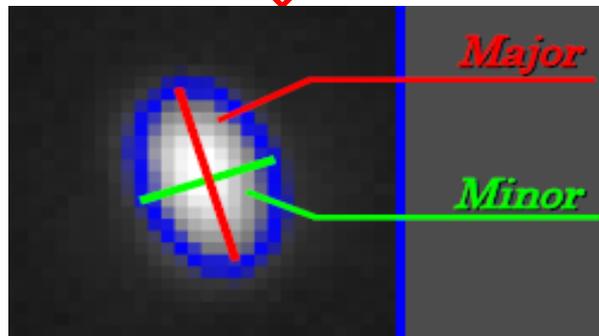

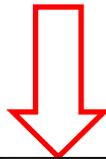

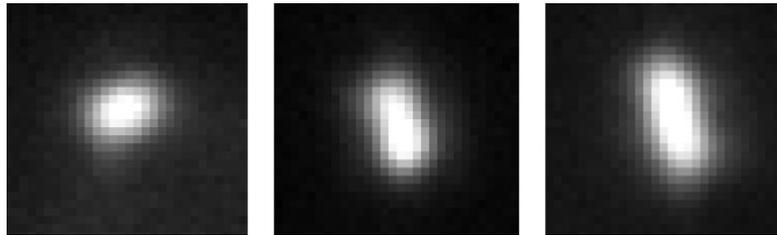

scanning speed is poor, but 1000

events /days observation is possible.

# Candidate selection for optical microscope system

## Example of nuclear recoil signal

2D\_Track length vs. Ellipticity

Current selection is used the simple elliptical shape

$\gamma/\beta$  events are expected to be distributed around Ellipticity of one.

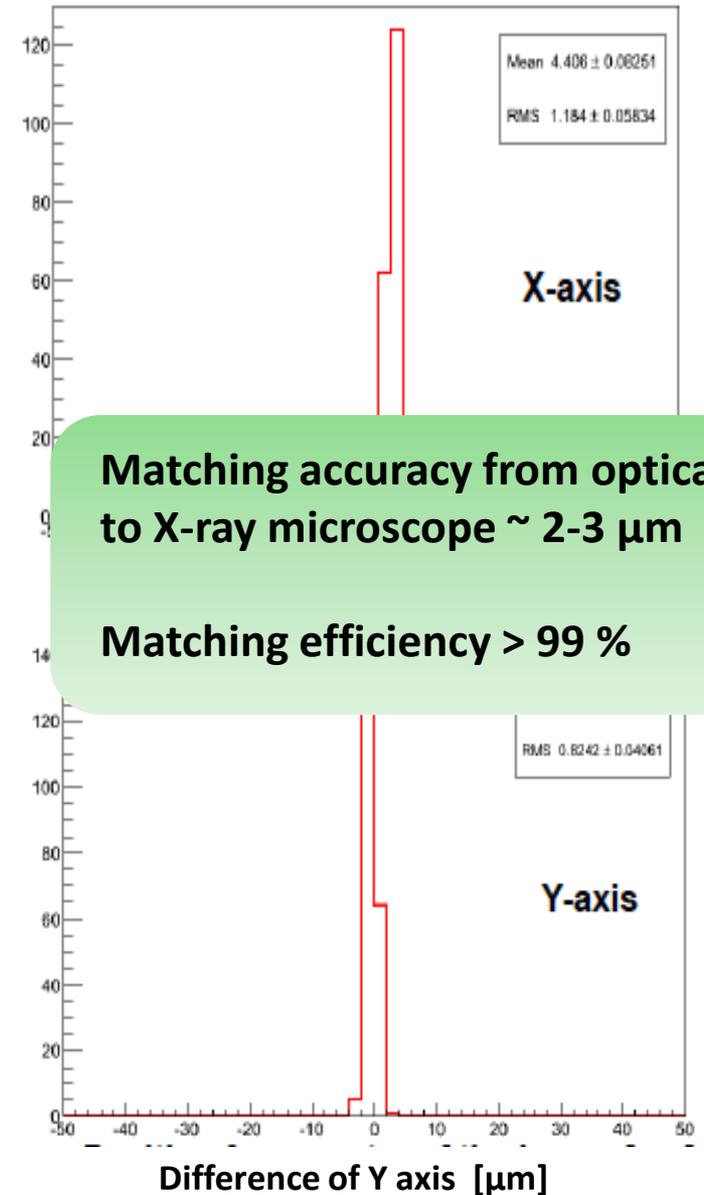

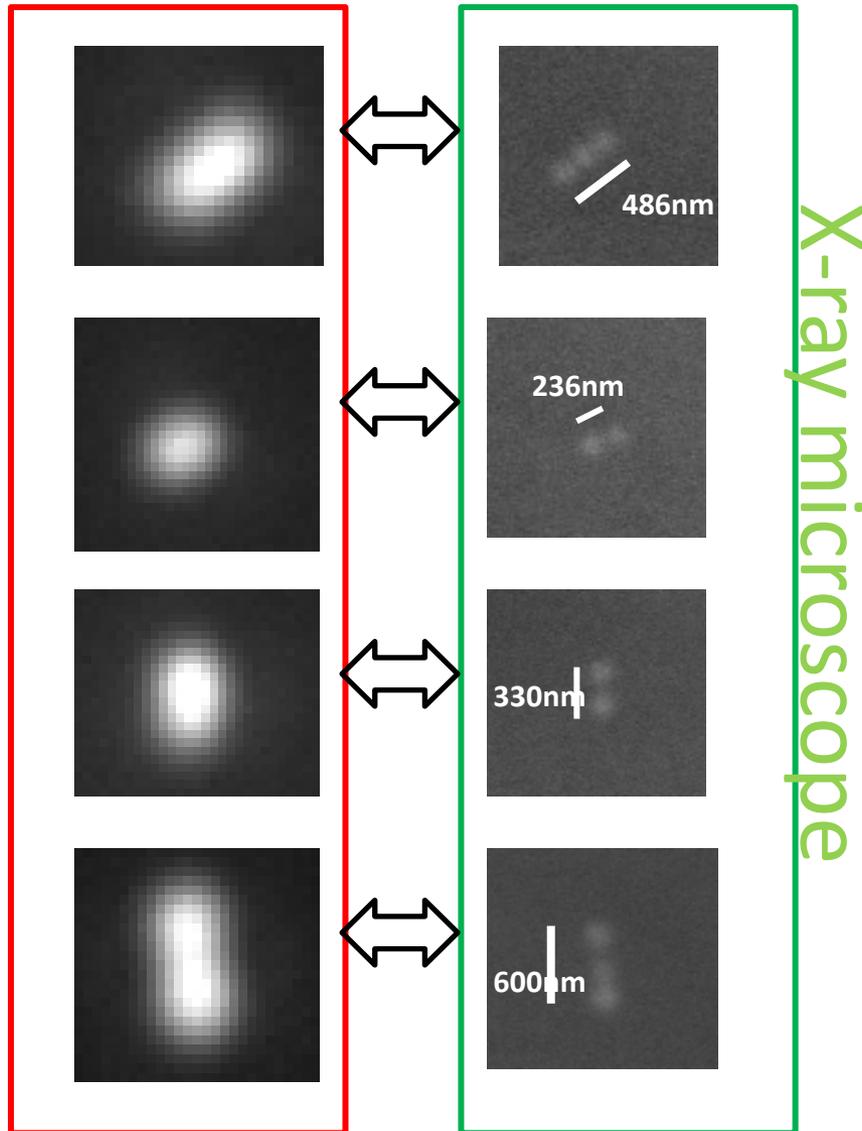

Another out put parameter

- position information
- brightness
- area of signals

**Preliminary rejection power of electrons is better than 1E-3 by using other parameter, but it is under study.**

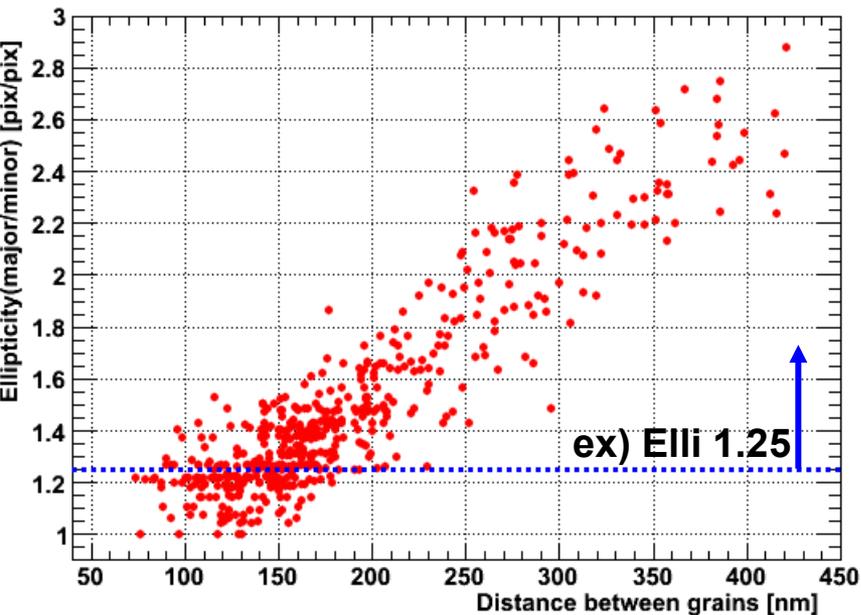

# Confirmation of selected candidate events by the X-ray microscope system

Optical microscope

Matching accuracy from optical to X-ray microscope  $\sim 2\text{-}3 \mu\text{m}$

Matching efficiency  $> 99 \%$

### Readout condition

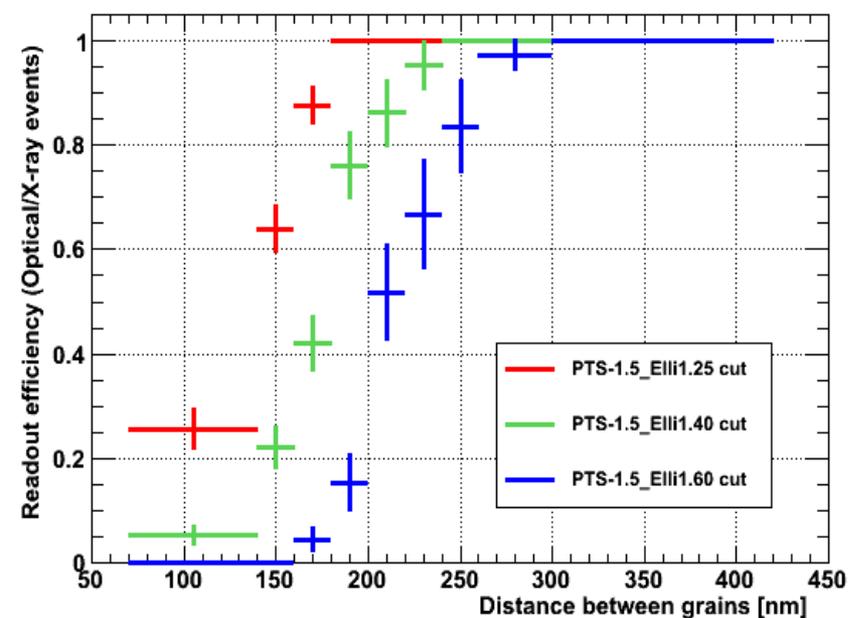

Wavelength : 450 nm (blue light)

N.A. (numerical apperture) of obj. lens : 1.4

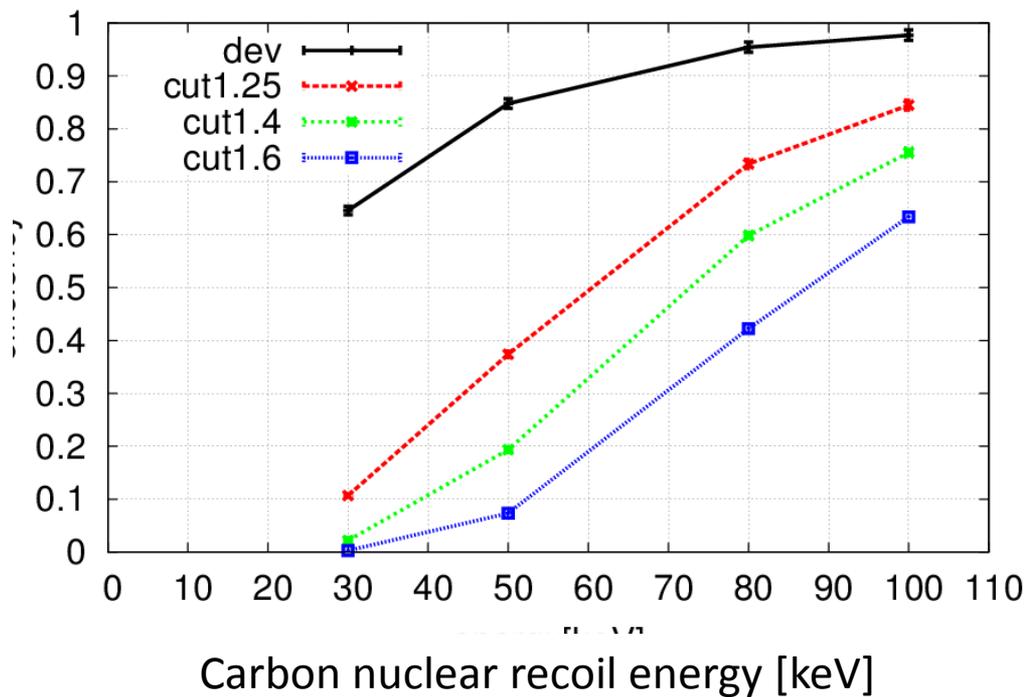

- ✓ > 170 nm tracks have 100 % readout efficiency.
- ✓ short length tracks (~ 100 nm) can be read out by mechanical expansion technique.

( M. Kimura and T. Naka, NIMA, Vol. 680,11 (2012))

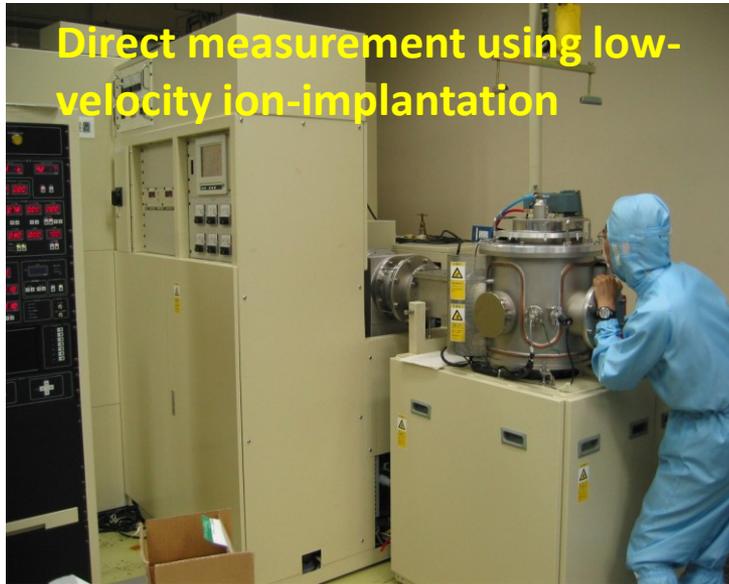

*readout efficiency\_F15-1.5(Ellipticity>=1.25,1.40,1.60 & minor>=4.0)*

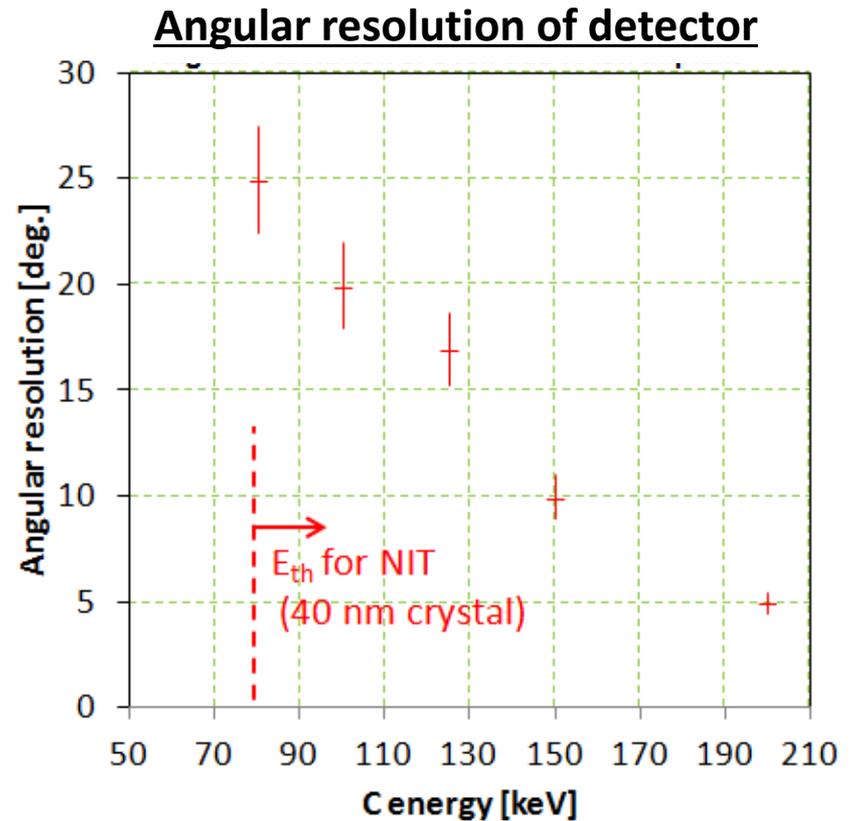

### Simulation of detector performance taken into account the readout efficiency

# Angular resolution for 40 nm crystal NIT

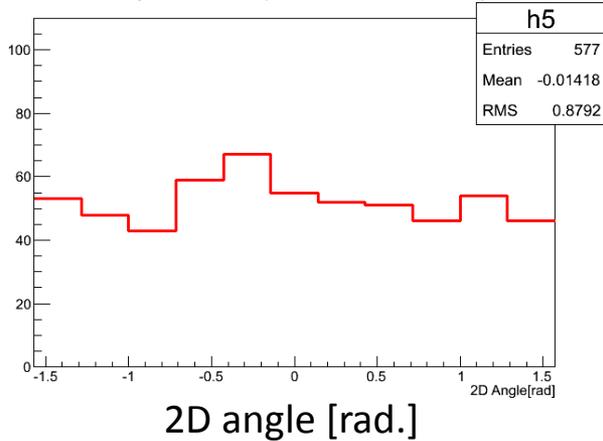

Accelerate voltage : > 10 keV (Max.200 kV)  
Type of ions : C, O, Ar (from CO<sub>2</sub>/Ar gas)  
Kr (from Kr gas), F, B (from BF<sub>3</sub> gas)  
IT is good calibration for direct detection of nuclear recoil because of uniform direction and energy.

# Demonstration of Angular Distribution Measurement

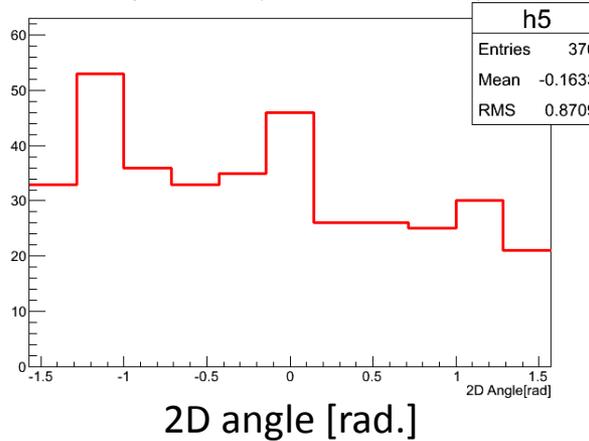

Mean range : 240 nm

2D Angle distribution(Minor>=5.0&&Elli>=1.25)

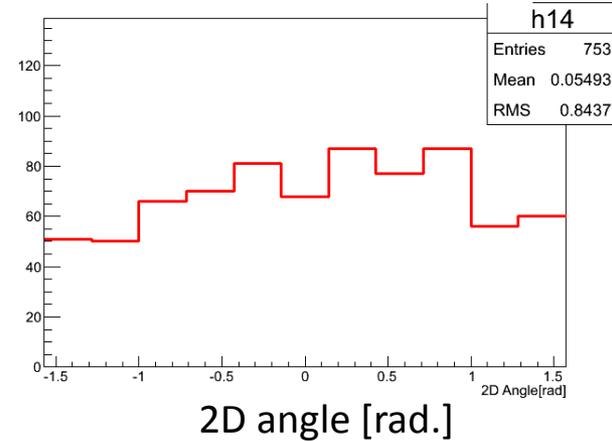

Mean range : 180 nm

2D Angle distribution(Minor>=5.0&&Elli>=1.25)

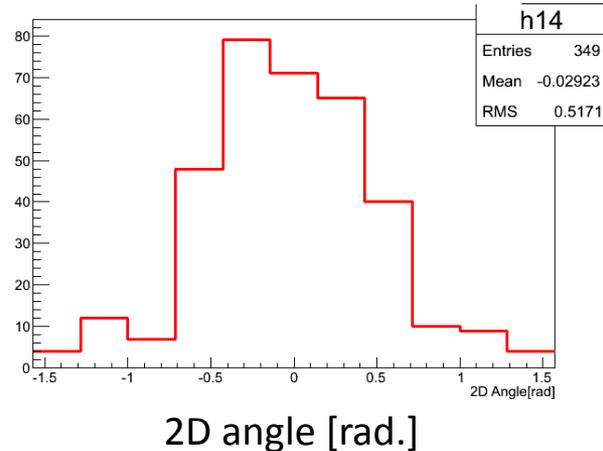

Mean range : 120 nm

2D Angle distribution(Minor>=5.0&&Elli>=1.25,shift)

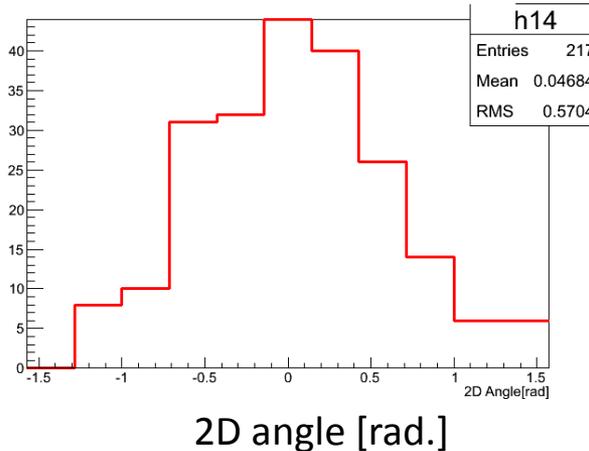

## Vertically Ion Exposure

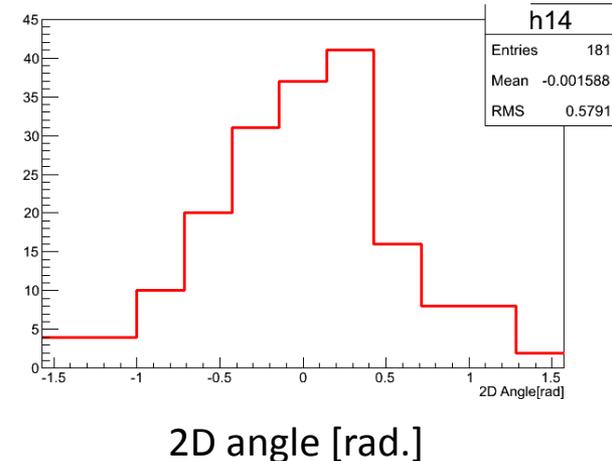

2D Angle distribution(Minor>=5.0&&Elli>=1.25,shift)

2D Angle distribution(Minor>=5.0&&Elli>=1.25,shift)

2D Angle distribution(Minor>=5.0&&Elli>=1.25,shift)

## Horizontally ion exposure

# Summary and Prospect

- Self-production of the super high resolution was achieved.

NIT : 40 nm crystal  $\Rightarrow$  ideal  $E_{th} > 25$  keV (2 grains) and  $> 50$  keV (3 grains) @ 50 % eff.

U-NIT: 20 nm crystal  $\Rightarrow$  ideal  $E_{th} > 15$  keV (2 grains) and  $> 30$  keV (3 grains) @ 50 % eff.

- Prototype Readout system started to run.

1. combined system with optical microscope  $\Leftrightarrow$  X-ray microscope
2. 100 % readout efficiency for  $> 170$  nm tracks
3. Angular resolution for NIT  $\Rightarrow$  better than 30 deg. at 80 keV  
C recoil.

## Future technology

Super-resolution readout method using Plasmon effect

$\Rightarrow$  50 nm resolution will be achieved in the optical microscope.

## Background rejection

we started the background measurement to understand the serious backgrounds

Now, we are developing the new device with threshold for  $dE/dx$  .
